Rapport de recherche n° 5780 — December 13, 2005 — 27 pages

**Abstract:** Using a support vector machine requires to set two types of hyperparameters: the soft margin parameter  $C$  and the parameters of the kernel. To perform this model selection task, one can use various procedures based on cross-validation. Obviously, the major drawback of such procedures rests in their time requirements. To overcome this difficulty, several upper bounds on the leave-one-out error of pattern recognition support vector machines have been derived. In this report, we demonstrate a direct extension of one of these bounds, called the radius-margin bound, to the case of the standard multi-class SVM.

**Key-words:** Leave-one-out error, SVMs, M-SVMs, model selection.

## Borne "rayon-marge" sur l'erreur "leave-one-out" des SVM multi-classes

**Résumé :** L'utilisation d'une machine à vecteurs support requiert la détermination des valeurs de deux types d'hyper-paramètres : le paramètre de "marge molle"  $C$  et les paramètres du noyau. Pour effectuer cette tâche de sélection de modèle, différentes procédures fondées sur la validation croisée sont actuellement disponibles. Leur défaut premier réside dans le temps de calcul qu'elles nécessitent. Afin de surmonter cette difficulté, différentes bornes supérieures sur l'erreur "leave-one-out" des SVM calculant des dichotomies ont été proposées. Dans ce rapport, nous établissons une extension directe de l'une de ces bornes, nommée borne "rayon-marge", au cas de la SVM multi-classe standard.

**Mots-clés :** Erreur "leave-one-out", SVM, M-SVM, sélection de modèle.

## 1 Introduction

Using a support vector machine requires to set two types of hyperparameters: the soft margin parameter  $C$  and the parameters of the kernel. To perform this model selection task, several approaches are available ([7, 8]). A simple solution consists in applying a cross-validation procedure. This, however, can appear highly time consuming, especially if the procedure is a leave-one-out one. This is the reason why, in recent years, a number of upper bounds on the leave-one-out error of bi-class SVMs have been proposed in literature (see for instance [11, 12, 9]). Unfortunately, so far, little has been done to extend them to the multi-class case. A notable exception is the work Wang and co-workers [13]. The authors propose two extensions of Chapelle's "radius-margin bound" [10, 11, 3]. However, to preserve the appealing properties of the original (bi-class) result, they deviate significantly from a direct extension. As they put it themselves: "However, a direct extension of this bound to the multi-class scenario is not viable because it is rooted in the theoretical results of bi-class SVMs."

In this report, we introduce a direct extension of the radius-margin bound to the multi-class case. This leads us to introduce original concepts, such as the one of margins for multi-class SVMs. It appears once more that the statistical theory of multi-category discriminant analysis cannot be built as a trivial generalization of the theory developed for the computation of dichotomies. Our bound, when applied in the bi-class case, should be sharper than the original one, although this is obtained at a significant additional cost.

The organization of this document is as follows. Section 2 introduces the bi-class SVMs, summarizing their architecture and training algorithm. A detailed proof of the original bound is then presented in Section 3. In Section 4, the standard multi-class SVM is introduced. The extension of the RM Theorem to this machine is the subject of Section 5.

## 2 Bi-class SVMs

### 2.1 Architecture and algorithm

We first summarize the main points of the training algorithm of pattern recognition SVMs ([1, 4]). A SVM is characterized by a kernel  $\kappa \rightarrow \mathcal{X}^2$  (one projection operator of which we call  $\Phi$ ) and a soft margin constant  $C$ . Suppose that it is trained on a subset  $s_m = \{(x_i, y_i)\}$ , ( $1 \leq i \leq m$ ) of  $\mathcal{X} \times \{-1, 1\}$ . The algorithm constructs an *optimal hyperplane*, that is to say an hyperplane maximizing the "margin". The "margin" is the smallest Euclidean distance of a point of the training set to the hyperplane, the equation of which is  $\langle w^0, \Phi(x) \rangle + b^0 = 0$ . Moreover, this optimal hyperplane is expressed in its canonical form ([10], p.412) i.e.

$$\min_x \|\langle w, \Phi(x) \rangle + b\| = 1.$$

The hyperplane is thus the solution of the following Quadratic Programming (QP) problem<sup>1</sup>:

**Problem 1**

$$\begin{aligned} \min_{w,b} & \left\{ \frac{1}{2} \|w\|^2 + C \sum_{i=1}^m \xi_i \right\} \\ \text{s.t.} & \begin{cases} y_i(\langle w, \Phi(x_i) \rangle + b) \geq 1 - \xi_i, & (1 \leq i \leq m) \\ \xi_i \geq 0, & (1 \leq i \leq m) \end{cases} \end{aligned}$$

The couple  $(w^0, b^0)$  is the solution of this optimization problem. The Lagrangian function associated with Problem 1 is given by:

$$L(w, b, \xi, \alpha, \beta) = \frac{1}{2} \|w\|^2 + C \sum_{i=1}^m \xi_i - \sum_{i=1}^m \alpha_i (y_i(\langle w, \Phi(x_i) \rangle + b) - 1 + \xi_i) - \sum_{i=1}^m \beta_i \xi_i. \quad (1)$$

Setting the gradient of (1) with respect to  $w$  equal to the null vector gives the expression of  $w$  as a function of the Lagrange multipliers  $\alpha_i$  which is:

$$w = \sum_{i=1}^m y_i \alpha_i \Phi(x_i). \quad (2)$$

Setting the gradient of (1) with respect to  $b$  equal to the null vector gives

$$\sum_{i=1}^m y_i \alpha_i = 0. \quad (3)$$

---

<sup>1</sup>The notions of mathematical programming used in this report can be found, for example, in [5].

Setting the gradient of (1) with respect to the slack variables  $\xi_i$  equal to the null vector gives

$$\alpha_i + \beta_i = C, \quad (1 \leq i \leq m). \quad (4)$$

Substituting (2) and using (3) and (4) in (1) leads to the Wolfe-dual formulation of Problem 1, the constraints of which are deduced from (3) and (4):

**Problem 2**

$$\begin{aligned} \max_{\alpha} \quad & \left\{ -\frac{1}{2} \sum_{i=1}^m \sum_{j=1}^m \alpha_i \alpha_j y_i y_j \kappa(x_i, x_j) + \sum_{i=1}^m \alpha_i \right\} \\ \text{s.t.} \quad & \begin{cases} 0 \leq \alpha_i \leq C, \quad (1 \leq i \leq m) \\ \sum_{i=1}^m \alpha_i y_i = 0 \end{cases}. \end{aligned}$$

The objective function of this latter problem can be reformulated as

$$J(\alpha) = -\frac{1}{2} \alpha^T H \alpha + 1^T \alpha$$

where the general term of the Hessian matrix  $H$  is given by  $h_{i,j} = y_i y_j \kappa(x_i, x_j)$ . Let  $\alpha^0 = [\alpha_1^0, \dots, \alpha_m^0]^T$  be the optimal solution of Problem 2. According to (2), the expression of  $w^0$  is:

$$w^0 = \sum_{i=1}^m y_i \alpha_i^0 \Phi(x_i). \quad (5)$$

## 2.2 Some useful results

We introduce some results needed in the proofs of the key lemma and RM Theorem. First, note that the general term of vector  $1 - H\alpha^0$  is simply

$$1 - \sum_{j=1}^m \alpha_j^0 y_j y_i \kappa(x_j, x_i) = 1 - y_i \langle w^0, \Phi(x_i) \rangle = y_i b^0 + \xi_i^0. \quad (6)$$

**Proposition 1** *In the separable cas, we have:*

$$\alpha^{0T} H \alpha^0 = \|w^0\|^2 = \sum_{i=1}^m \alpha_i^0 = \frac{1}{\gamma^2} \quad (7)$$

with  $\gamma$  the margin.

**Proof**

- $\alpha^0{}^T H \alpha^0 = \|w^0\|^2$

Actually, for any vector  $z$  of size  $m$  the components of which are  $z_i$ , we have:

$$z^T H z = \sum_{i=1}^m \sum_{j=1}^m z_i h_{ij} z_j = \sum_{i=1}^m \sum_{j=1}^m z_i z_j y_i y_j \kappa(x_i, x_j). \quad (8)$$

Since  $\kappa(x_i, x_j) = \langle \Phi(x_i), \Phi(x_j) \rangle$ ,

$$z^T H z = \left\| \sum_{i=1}^m z_i y_i \Phi(x_i) \right\|^2. \quad (9)$$

Hence, when  $z$  is an optimal solution of Problem 2, this directly leads to the expression of  $\|w^0\|^2$ .

- $\|w^0\|^2 = \sum_{i=1}^m \alpha_i^0$

Since  $\forall i \quad \xi_i = 0$ , the Kuhn-Tucker conditions imply that

$$\alpha_i^0 (1 - y_i (\langle w^0, \Phi(x_i) \rangle + b^0)) = 0.$$

Thus

$$\sum_{i=1}^m \alpha_i^0 (1 - y_i (\langle w^0, \Phi(x_i) \rangle + b^0)) = 0.$$

This is equivalent to:

$$\sum_{i=1}^m \alpha_i^0 - b^0 \sum_{i=1}^m \alpha_i^0 y_i - \langle w^0, \sum_{i=1}^m \alpha_i^0 y_i \Phi(x_i) \rangle = 0.$$

Simplifying with the use of (3) and (5), we get:

$$\sum_{i=1}^m \alpha_i^0 - \|w^0\|^2 = 0.$$

- $\|w^0\|^2 = \frac{1}{\gamma^2}$

This springs directly from the fact that the hyperplane is expressed in its canonical form.

■

### 3 Bi-class radius-margin bound

#### 3.1 Key lemma in the bi-class case

In this section we introduce the key lemma which is a basis for the proof of the RM Theorem.

**Lemma 1** *Let us consider a pattern recognition SVM on a domain  $\mathcal{X}$ . This SVM is characterized by a kernel  $\kappa$  (a projection operator  $\Phi$ ) and a soft margin constant  $C$ . Suppose that it is trained on a subset  $s_m = \{(x_i, y_i)\}$ ,  $(1 \leq i \leq m)$  of  $\mathcal{X} \times \{-1, 1\}$ , the points of which it separates without error. Suppose further that all the corresponding dual variables  $\alpha_i^0$  satisfy  $\alpha_i^0 < C$ . Consider now the same machine, trained on  $s_m \setminus \{(x_p, y_p)\}$ . If it makes an error on  $(x_p, y_p)$ , then the inequality*

$$\alpha_p^0 \geq \frac{1}{\mathcal{D}_m^2} \quad (10)$$

*holds, where  $\mathcal{D}_m$  is the diameter of the smallest sphere containing the projections of the support vectors of the initial machine in the feature space.*

**Proof** First, note that support vectors are points  $x_i$  verifying:

$$0 < \alpha_i^0 \quad (11)$$

which, given the hypotheses, implies that  $0 < \alpha_i^0 < C$ .

The hypotheses of Lemma 1 also implicitly imply the fact that  $\alpha_p^0 \neq 0$ , of which we will make use several times. Let  $(w^p, b^p)$  be the couple characterizing the optimal hyperplane when the machine is trained on  $s_m \setminus \{(x_p, y_p)\}$ . Assuming that this machine makes an error on the example  $(x_p, y_p)$  means that

$$y_i(\langle w^p, \Phi(x_i) \rangle + b^p) < 0.$$

Let  $\alpha^p = [\alpha_1^p, \dots, \alpha_{p-1}^p, 0, \alpha_{p+1}^p, \dots, \alpha_m^p]^T$  be the vector of  $[0, C)^m$  the components of which are the dual variables of the second SVM, with a 0 in position  $p$ . This representation is used to characterize directly the second SVM with respect to the first one. Indeed,  $\alpha^p$  is an optimal solution of Problem 2 under the additional constraint  $\alpha_p^p = 0$ . Let us define two more vectors in  $\mathbb{R}_+^m$ ,  $\lambda^p = [\lambda_i^p]$  and  $\mu^p = [\mu_i^p]$ .  $\lambda^p$  is constructed in such a way that the vector  $\alpha^0 - \alpha_p^0 \lambda^p$  is a feasible solution of Problem 2 under the additional constraint that  $\alpha_p^0 - \alpha_p^0 \lambda_p^p = 0$ , i.e.  $\alpha^0 - \alpha_p^0 \lambda^p$  satisfies the same constraints as  $\alpha^p$ . We have thus:

$$\forall i \neq p, \quad \alpha_i^0 - \alpha_p^0 \lambda_i^p \geq 0 \iff \lambda_i^p \leq \frac{\alpha_i^0}{\alpha_p^0}$$

$$\forall i \neq p, \quad \lambda_i^p \geq 0 \implies \alpha_i^0 - \alpha_p^0 \lambda_i^p \leq C$$

$$\alpha_p^0 - \alpha_p^0 \lambda_p^p = 0 \iff \lambda_p^p = 1.$$

Using (3), we have:

$$\sum_{i=1}^m y_i (\alpha_i^0 - \alpha_p^0 \lambda_i^p) = 0 \iff \alpha_p^0 \sum_{i=1}^m y_i \lambda_i^p = 0 \iff \sum_{i=1}^m y_i \lambda_i^p = 0.$$

Vector  $\lambda^p$  satisfies the following properties:

$$\begin{cases} \lambda_p^p = 1 \\ \forall i, 0 \leq \lambda_i^p \leq \frac{\alpha_i^0}{\alpha_p^0} \\ \sum_{i=1}^m y_i \lambda_i^p = 0 \end{cases} . \quad (12)$$

In addition, we assign nonzero values only to some coordinates of  $\lambda^p$  (apart from  $\lambda_p^p$ ) that correspond to points the class of which is the opposite of the class of  $x_p$ . Note that for any point  $x_i$  that is not a support vector, we have  $\alpha_i^0 = 0$  and consequently  $\lambda_i^p = 0$ . Our set of points for which  $\lambda_i^p \neq 0$  is thus a subset of the set of support vectors. To sum up, vector  $\lambda^p$  satisfies the following properties:

$$\begin{cases} y_i = y_p \begin{cases} i = p, & \lambda_i^p = 1 \\ i \neq p, & \lambda_i^p = 0 \end{cases} \\ y_i \neq y_p, 0 \leq \lambda_i^p \leq \frac{\alpha_i^0}{\alpha_p^0} \\ \sum_{i=1}^m y_i \lambda_i^p = 0 \end{cases} . \quad (13)$$

Quite similarly to  $\lambda^p$ ,  $\mu^p$  is specified so that  $\alpha^p + c\mu^p$  satisfies the same constraints as  $\alpha^0$ , where  $c$  is a scalar belonging to  $(0, C]$ . Furthermore, we impose that  $\mu_p^p = 1$ . First, note that, as required,

$$\forall i \neq p, \mu_i^p \geq 0 \implies \alpha_i^p + c\mu_i^p \geq 0$$

and

$$\alpha_p^p + c\mu_p^p = c \implies 0 \leq \alpha_p^p + c\mu_p^p \leq C.$$

The remaining constraints are expressed as:

$$\begin{aligned} \sum_{i=1}^m y_i (\alpha_i^p + c\mu_i^p) = 0 &\iff \sum_{i=1}^m y_i \mu_i^p = 0, \\ \forall i \neq p, \alpha_i^p + c\mu_i^p \leq C &\iff \mu_i^p \leq \frac{C - \alpha_i^p}{c}. \end{aligned}$$

Note that since all the  $\alpha_i^0$  are strictly inferior to  $C$ , changing  $C$  for a larger value  $C'$  does not change the optimal solution of Problem 2. As a consequence, without loss of generality we can make the hypothesis that  $C$  is arbitrarily large. The last constraint thus vanishes. Performing as in the case of  $\lambda^p$ , we assign nonzero values only to some coordinates of  $\mu^p$  (apart from  $\mu_p^p$ ) that correspond to support vectors of  $(w^0, b^0)$  the class of which is the

opposite of the class of  $x_p$ . The reason for this choice will appear at the end of the proof. Finally, vector  $\mu^p$  satisfies the following properties:

$$\left\{ \begin{array}{l} y_i = y_p \begin{cases} i = p, & \mu_i^p = 1 \\ i \neq p, & \mu_i^p = 0 \end{cases} \\ y_i \neq y_p \begin{cases} \alpha_i^0 = 0, & \mu_i^p = 0 \\ \alpha_i^0 > 0, & \mu_i^p \geq 0 \end{cases} \\ \sum_{i=1}^m y_i \mu_i^p = 0 \end{array} \right. . \quad (14)$$

By construction of vectors  $\lambda^p$  and  $\mu^p$ , we have  $J(\alpha^0 - \alpha_p^0 \lambda^p) \leq J(\alpha^p)$  and  $J(\alpha^p + c\mu^p) \leq J(\alpha^0)$ , and by way of consequence,

$$J(\alpha^0) - J(\alpha^0 - \alpha_p^0 \lambda^p) \geq J(\alpha^0) - J(\alpha^p) \geq J(\alpha^p + c\mu^p) - J(\alpha^p). \quad (15)$$

Since

$$J(\alpha^0 - \alpha_p^0 \lambda^p) = -\frac{1}{2}(\alpha^0 - \alpha_p^0 \lambda^p)^T H(\alpha^0 - \alpha_p^0 \lambda^p) + 1^T(\alpha^0 - \alpha_p^0 \lambda^p),$$

the expression of the first term is

$$J(\alpha^0) - J(\alpha^0 - \alpha_p^0 \lambda^p) = \frac{(\alpha_p^0)^2}{2} \lambda^{pT} H \lambda^p + \alpha_p^0 \lambda^{pT} (1 - H \alpha^0).$$

But recalling (6) and (13) this can be simplified:

$$\lambda^{pT} (1 - H \alpha^0) = b^0 \sum_{i=1}^m y_i \lambda_i^p + \sum_{i=1}^m \lambda_i^p \xi_i^0 = \sum_{i=1}^m \lambda_i^p \xi_i^0. \quad (16)$$

At this point, we make use of the hypothesis that all the dual variables  $\alpha_i^0$  are strictly inferior to  $C$ . According to the Kuhn-Tucker conditions, this implies that all the slack variables  $\xi_i^0$  are equal to 0. Thus, the expression of  $J(\alpha^0) - J(\alpha^0 - \alpha_p^0 \lambda^p)$  is simply (recalling (9))

$$J(\alpha^0) - J(\alpha^0 - \alpha_p^0 \lambda^p) = \frac{(\alpha_p^0)^2}{2} \lambda^{pT} H \lambda^p = \frac{1}{2} (\alpha_p^0)^2 \left\| \sum_{i=1}^m \lambda_i^p y_i \Phi(x_i) \right\|^2. \quad (17)$$

We now turn to the right-hand side of (15), directly simplifying it thanks to (9).

$$J(\alpha^p + c\mu^p) - J(\alpha^p) = c\mu^{pT} (1 - H \alpha^p) - \frac{c^2}{2} \left\| \sum_{i=1}^m \mu_i^p y_i \Phi(x_i) \right\|^2.$$

Proceeding as in the case of the left-hand side of (15), we establish that

$$\mu^{pT} (1 - H \alpha^p) = b_p \sum_{i=1}^m y_i \mu_i^p + \sum_{i=1}^m \mu_i^p \xi_i^p = \sum_{i=1}^m \mu_i^p \xi_i^p.$$

If the initial SVM, characterized by the couple  $(w^0, b^0)$ , has nothing but null slack variables, then the sole slack variable of the SVM  $(w^p, b^p)$  which can be positive is  $\xi_p^p$ . Thus as in (16),

$$\mu^{pT} (1 - H\alpha^p) = \xi_p^p = 1 - y_p (\langle w^p, \Phi(x_p) \rangle + b^p)$$

and by way of consequence

$$J(\alpha^p + c\mu^p) - J(\alpha^p) = c [1 - y_p (\langle w^p, \Phi(x_p) \rangle + b^p)] - \frac{c^2}{2} \left\| \sum_{i=1}^m \mu_i^p y_i \Phi(x_i) \right\|^2. \quad (18)$$

Combining (17) and (18) finally gives:

$$\frac{1}{2}(\alpha_p^0)^2 \left\| \sum_{i=1}^m \lambda_i^p y_i \Phi(x_i) \right\|^2 \geq c [1 - y_p (\langle w^p, \Phi(x_p) \rangle + b^p)] - \frac{c^2}{2} \left\| \sum_{i=1}^m \mu_i^p y_i \Phi(x_i) \right\|^2. \quad (19)$$

We want to find the best lower bound on the left-hand side of this inequality (or more precisely  $\alpha_p^0$ ), thus we look for the maximum of the right-hand side with respect to  $c$ . On  $\mathbb{R}_+^*$  this maximum is obtain for:

$$c^* = \frac{1 - y_p (\langle w^p, \Phi(x_p) \rangle + b^p)}{\left\| \sum_{i=1}^m \mu_i^p y_i \Phi(x_i) \right\|^2}.$$

To understand why we maximize on  $\mathbb{R}_+^*$  rather than on  $(0, C]$ , remember that without loss of generality we can make the hypothesis that  $C$  is arbitrarily large, which exonerates us from checking that  $c^* < C$ . By substitution in (19),  $(\alpha_p^0)^2$  can thus be bounded from below as follows:

$$(\alpha_p^0)^2 \geq \frac{[1 - y_p (\langle w^p, \Phi(x_p) \rangle + b^p)]^2}{\left\| \sum_{i=1}^m \lambda_i^p y_i \Phi(x_i) \right\|^2 \left\| \sum_{i=1}^m \mu_i^p y_i \Phi(x_i) \right\|^2}.$$

Since by hypothesis the SVM  $(w^p, b^p)$  misclassifies  $x_p$ ,  $[1 - y_p (\langle w^p, \Phi(x_p) \rangle + b^p)]^2 > 1$ . This provides us with a simpler lower bound on  $(\alpha_p^0)^2$ , namely

$$(\alpha_p^0)^2 \geq \frac{1}{\left\| \sum_{i=1}^m \lambda_i^p y_i \Phi(x_i) \right\|^2 \left\| \sum_{i=1}^m \mu_i^p y_i \Phi(x_i) \right\|^2}. \quad (20)$$

Recalling the constraints assigning nonzero values only to some coordinates of  $\lambda_p$  and  $\mu_p$  that correspond to support vectors the class of which is the opposite of the class of  $x_p$ , the terms in the denominator of (20) appear as the difference between two vectors. One of these vectors (in both cases) is  $\Phi(x_p)$ , whereas the other one is a convex combination, in the feature space, of support vectors of the opposite class (here appears the interest of the additional constraints on  $\mu^p$ ). As a consequence, both vectors belong to the smallest ball

containing the support vectors of  $(w^0, b^0)$ . By application of the triangle inequality, we thus obtain:

$$\left\| \sum_{i=1}^m \lambda_i^p y_i \Phi(x_i) \right\|^2 \leq \mathcal{D}_m^2, \quad \left\| \sum_{i=1}^m \mu_i^p y_i \Phi(x_i) \right\|^2 \leq \mathcal{D}_m^2. \quad (21)$$

Thanks to (21), it is possible to substitute both  $\left\| \sum_{i=1}^m \lambda_i^p y_i \Phi(x_i) \right\|^2$  and  $\left\| \sum_{i=1}^m \mu_i^p y_i \Phi(x_i) \right\|^2$  with  $\mathcal{D}_m^2$  in (20), which concludes the proof. ■

### 3.2 RM theorem

**Theorem 1** *Let us consider a pattern recognition SVM on a domain  $\mathcal{X}$ . This SVM is characterized by a kernel  $\kappa$  (a projection operator of which we call  $\Phi$ ) and a soft margin constant  $C$ . Suppose that it is trained on a subset  $s_m = \{(x_i, y_i)\}$ ,  $(1 \leq i \leq m)$  of  $\mathcal{X} \times \{-1, 1\}$ , the points of which it separates without error. Suppose further that all the corresponding dual variables  $\alpha_i^0$  satisfy  $\alpha_i^0 < C$ . Let  $\mathcal{L}_m$  be the number of errors resulting from applying a leave-one-out procedure to this machine,  $\mathcal{D}_m$  the diameter of the smallest ball containing the support vectors of the initial machine and  $\gamma$  its margin. We have:*

$$\mathcal{L}_m \leq \frac{\mathcal{D}_m^2}{\gamma^2}. \quad (22)$$

**Proof** Actually, the key lemma exhibits a non-trivial bound on  $\alpha_i^0$  when the machine trained on the set without  $(x_i, y_i)$  makes an error on this point. Thus, the sum of the  $\alpha_i^0$  is constituted of the terms we can bound thanks to the key lemma ( $\alpha_i^0 \geq \frac{1}{\mathcal{D}_m^2}$ ) and the others with the trivial bound ( $\alpha_i^0 \geq 0$ ). We have thus:

$$\sum_{i=1}^m \alpha_i^0 \geq \frac{\mathcal{L}_m}{\mathcal{D}_m^2},$$

and consequently:

$$\mathcal{L}_m \leq \mathcal{D}_m^2 \sum_{i=1}^m \alpha_i^0.$$

Since we are in the separable case, we can use the right-hand side equality of (7) and conclude:

$$\mathcal{L}_m \leq \frac{\mathcal{D}_m^2}{\gamma^2}. \quad \blacksquare$$

## 4 Multi-class SVMs

There are several types of multi-class SVMs (see [6] for a survey). We will focus here on the machine introduced independently and under different forms in [14, 10, 2]. For the sake of simplicity, we will only refer to it as "the" M-SVM in the sequel.

### 4.1 Architecture and algorithm

We first summarize the main points of the training algorithm of this machine. Let us consider a M-SVM on a domain  $\mathcal{X}$ . It is characterized by a kernel  $\kappa$  (a projection operator of which is  $\Phi$ ) and a soft margin constant  $C$ . Let  $\mathcal{C} = \{C_k\}$ , ( $1 \leq k \leq Q$ ) be the set of categories. Suppose that the machine is trained on a set  $s_m = \{(x_i, C(x_i))\}$ , ( $1 \leq i \leq m$ ) of  $m$  couples in  $\mathcal{X} \times \mathcal{C}$ . The algorithm constructs a set of optimal hyperplanes  $(w_k, b_k)$ , ( $1 \leq k \leq Q$ ), by solving a QP problem. Let  $W = \{w_1, \dots, w_k, \dots, w_Q\}$  and  $b = \{b_1, \dots, b_k, \dots, b_Q\}$ . The model corresponds to the class of functions  $h$ :

$$\forall x \in \mathcal{X}, \quad h(x) = \begin{bmatrix} \langle w_1, \Phi(x) \rangle \\ \vdots \\ \langle w_k, \Phi(x) \rangle \\ \vdots \\ \langle w_Q, \Phi(x) \rangle \end{bmatrix} + \begin{bmatrix} b_1 \\ \vdots \\ b_k \\ \vdots \\ b_Q \end{bmatrix}. \quad (23)$$

This QP problem is the following one:

**Problem 3**

$$\min_{W, b} \left\{ \frac{1}{2} \sum_{k=1}^Q \|w_k\|^2 + C \sum_{i=1}^m \sum_{k=1, k \neq C(x_i)}^Q \xi_{ik} \right\}$$

$$s.t. \begin{cases} \langle w_{C(x_i)} - w_k, \Phi(x_i) \rangle + b_{C(x_i)} - b_k \geq 1 - \xi_{ik}, & (1 \leq i \leq m), (1 \leq k \neq C(x_i) \leq Q) \\ \xi_{ik} \geq 0, & (1 \leq i \leq m), (1 \leq k \neq C(x_i) \leq Q) \end{cases}.$$

Let the couple  $(W^0, b^0)$  denote the solution of this optimization problem. The Lagrangian function associated with Problem 3 is given by:

$$L(W, b, \xi, \alpha, \beta) =$$

$$\frac{1}{2} \sum_{k=1}^Q \|w_k\|^2 + C \sum_{i=1}^m \sum_{k=1}^Q \xi_{ik} - \sum_{i=1}^m \sum_{k=1}^Q \alpha_{ik} \{ \langle w_{C(x_i)} - w_k, \Phi(x_i) \rangle + b_{C(x_i)} - b_k - 1 + \xi_{ik} \}$$

$$- \sum_{i=1}^m \sum_{k=1}^Q \beta_{ik} \xi_{ik}. \quad (24)$$

Setting the gradient of (24) with respect to  $w_k$  equal to the null vector gives the expression of  $w_k$  as a function of the  $\alpha_{ik}$ , which is:

$$w_k = \sum_{x_i \in C_k} \sum_{l=1}^Q \alpha_{il} \Phi(x_i) - \sum_{i=1}^m \alpha_{ik} \Phi(x_i). \quad (25)$$

Setting the gradient of (24) with respect to  $b_k$  equal to the null vector gives

$$\sum_{x_i \in C_k} \sum_{l=1}^Q \alpha_{il} - \sum_{i=1}^m \alpha_{ik} = 0. \quad (26)$$

Setting the gradient of (24) with respect to  $\xi_k$  equal to the null vector gives

$$\alpha_{ik} + \beta_{ik} = C, \quad (1 \leq i \leq m), (1 \leq k \leq Q), k \neq C(x_i). \quad (27)$$

Substituting (25) and using (26) and (27) in (24) leads to the Wolfe-dual formulation of Problem 3, the constraints of which are deduced from (26) and (27):

**Problem 4**

$$\begin{aligned} & \max_{\alpha} \{J(\alpha)\} \\ \text{s.t. } & \begin{cases} 0 \leq \alpha_{ik} < C, \quad (1 \leq i \leq m), (1 \leq k \leq Q), k \neq C(x_i) \\ \sum_{x_i \in C_k} \sum_{l=1}^Q \alpha_{il} - \sum_{i=1}^m \alpha_{ik} = 0, \quad (1 \leq k \leq Q-1) \end{cases} \end{aligned}$$

where:

$$\begin{aligned} J(\alpha) = & -\frac{1}{2} \left\{ \sum_{i \simeq j} \sum_{k=1}^Q \sum_{l=1}^Q \alpha_{ik} \alpha_{jl} \kappa(x_i, x_j) - 2 \sum_{i=1}^m \sum_{j=1}^m \sum_{k=1}^Q \alpha_{ik} \alpha_{jC(x_i)} \kappa(x_i, x_j) + \sum_{i=1}^m \sum_{j=1}^m \sum_{k=1}^Q \alpha_{ik} \alpha_{jk} \kappa(x_i, x_j) \right\} \\ & + \sum_{i=1}^m \sum_{k=1}^Q \alpha_{ik}. \end{aligned}$$

with  $i \simeq j$  meaning that  $x_i$  and  $x_j$  belong to the same category.

In the formulation of Problem 4, we have implicitly introduced the dummy variables  $\alpha_{iC(x_i)} = 0$ ,  $(1 \leq i \leq m)$ . In what follows, they will be used again wherever they make notation simpler. The objective function can be expressed as

$$J(\alpha) = -\frac{1}{2} \alpha^T H \alpha + 1_{(Q-1)m}^T \alpha$$

where the general term of the Hessian matrix  $H$  can be found in the technical documentation of the M-SVM software ([http://www.loria.fr/~guermeur/technical\\_doc/index.html](http://www.loria.fr/~guermeur/technical_doc/index.html)).

Let  $\alpha^0 = [\alpha_{11}^0, \dots, \alpha_{1Q}^0, \dots, \alpha_{i1}^0, \dots, \alpha_{iQ}^0, \dots, \alpha_{mQ}^0]^T$  be the optimal solution of Problem 4. According to (25), the expression of  $w_k^0$  is then:

$$w_k^0 = \sum_{x_i \in C_k} \sum_{l=1}^Q \alpha_{il}^0 \Phi(x_i) - \sum_{i=1}^m \alpha_{ik}^0 \Phi(x_i). \quad (28)$$

**Definition 1 (Multi-class margin)**  $\gamma_{kl}$ , the margin between categories  $C_k$  and  $C_l$ , is defined as in the bi-class case as the smallest distance of a point either in  $C_k$  or  $C_l$  to the hyperplane separating those categories.

For  $1 \leq k < l \leq Q$ , let  $\delta_{kl}$  be:

$$\delta_{kl} = \min \left[ \left\{ \min_{x_i \in C_k} \langle w_k - w_l, \Phi(x_i) \rangle + b_k - b_l - 1, \min_{x_j \in C_l} \langle w_l - w_k, \Phi(x_j) \rangle + b_l - b_k - 1 \right\} \right]. \quad (29)$$

We have:

$$\gamma_{kl} = \frac{1 + \delta_{kl}}{\|w_k - w_l\|}. \quad (30)$$

Note that we know the values of the  $\delta_{kl}$  as soon as  $(w^0, b^0)$  is known.

## 4.2 Some useful results

We introduce some results needed in the proof of the extensions of the key lemma and the RM Theorem. Note that the general term of vector  $1 - H\alpha^0$  is simply  $\frac{\partial}{\partial \alpha_{ik}} J(\alpha^0)$ . It is thus equal to

$$1 - \left\{ \sum_{x_j \in C(x_i)} \sum_{l=1}^Q \alpha_{jl}^0 \kappa(x_j, x_i) - \sum_{j=1}^m \alpha_{jC(x_i)}^0 \kappa(x_j, x_i) - \sum_{x_j \in C_k} \sum_{l=1}^Q \alpha_{jl}^0 \kappa(x_j, x_i) + \sum_{j=1}^m \alpha_{jk}^0 \kappa(x_j, x_i) \right\}.$$

Keeping in mind the expression of the vectors defining the hyperplanes (25), this can be rewritten as

$$1 - \langle w_{C(x_i)}^0 - w_k^0, \Phi(x_i) \rangle = b_{C(x_i)}^0 - b_k^0 + \xi_{ik}^0. \quad (31)$$

Let us express the relationship between  $\sum_{k < l} \|w_k - w_l\|^2$  and  $\sum_{k=1}^Q \|w_k\|^2$ :

$$\sum_{k < l} \|w_k - w_l\|^2 = (Q-1) \sum_{k=1}^Q \|w_k\|^2 - 2 \sum_{k < l} \langle w_k, w_l \rangle. \quad (32)$$

Keeping in mind that  $\sum_{k=1}^Q w_k = 0$ , it springs that

$$\left\| \sum_{k=1}^Q w_k \right\|^2 = 0 = \sum_{k=1}^Q \sum_{l=1}^Q \langle w_k, w_l \rangle = \sum_{k=1}^Q \|w_k\|^2 + 2 \sum_{k < l} \langle w_k, w_l \rangle.$$

Thus,

$$\sum_{k=1}^Q \|w_k\|^2 = -2 \sum_{k < l} \langle w_k, w_l \rangle$$

which, by substitution in (32) leads to

$$\sum_{k < l} \|w_k - w_l\|^2 = Q \sum_{k=1}^Q \|w_k\|^2. \quad (33)$$

**Proposition 2** *We have:*

$$\alpha^0{}^T H \alpha^0 = \sum_{k=1}^Q \|w_k^0\|^2 = \sum_{i=1}^m \sum_{k=1}^Q \alpha_{ik}^0 = \frac{1}{Q} \sum_{k < l} \frac{(1 + \delta_{kl})^2}{\gamma_{kl}^2}. \quad (34)$$

**Proof**

- $\alpha^0{}^T H \alpha^0 = \sum_{k=1}^Q \|w_k^0\|^2$

Given the equality between the primal and the dual objective functions at the optimum, we have:

$$-\frac{1}{2} \alpha^0{}^T H \alpha^0 + 1_{(Q-1)m}^T \alpha = \frac{1}{2} \sum_{k=1}^Q \|w_k^0\|^2 + C \sum_{i=1}^m \sum_{k=1}^Q \xi_{ik}^0.$$

Combining it with (31), recalling that the  $\xi_{ik}^0$  are null,

$$-\frac{1}{2} \alpha^0{}^T H \alpha^0 = \frac{1}{2} \sum_{k=1}^Q \|w_k^0\|^2 - \sum_{i=1}^m \sum_{k=1}^Q \alpha_{ik}^0 \left\{ \langle w_{C(x_i)} - w_k, \Phi(x_i) \rangle + b_{C(x_i)}^0 - b_k^0 \right\}. \quad (35)$$

We have:

$$\sum_{i=1}^m \sum_{k=1}^Q \alpha_{ik}^0 (b_{C(x_i)}^0 - b_k^0) = \sum_{l=1}^Q \left\{ \sum_{x_i \in C_l} \sum_{k=1}^Q \alpha_{ik}^0 - \sum_{i=1}^m \alpha_{il}^0 \right\} b_l,$$

which, due to (26), implies

$$\sum_{i=1}^m \sum_{k=1}^Q \alpha_{ik}^0 (b_{C(x_i)}^0 - b_k^0) = 0. \quad (36)$$

(35) thus simplifies into:

$$-\frac{1}{2} \alpha^0{}^T H \alpha^0 = \frac{1}{2} \sum_{k=1}^Q \|w_k^0\|^2 - \sum_{i=1}^m \sum_{k=1}^Q \alpha_{ik}^0 \langle w_{C(x_i)}^0 - w_k^0, \Phi(x_i) \rangle. \quad (37)$$

Given (25),

$$\begin{aligned} \|w_k^0\|^2 = & \langle \sum_{x_i \in C_k} \sum_{l=1}^Q \alpha_{il}^0 \Phi(x_i) - \sum_{i=1}^m \alpha_{ik}^0 \Phi(x_i), \sum_{x_j \in C_k} \sum_{n=1}^Q \alpha_{jn}^0 \Phi(x_j) - \sum_{j=1}^m \alpha_{jk}^0 \Phi(x_j) \rangle = \\ & \sum_{x_i \in C_k} \sum_{x_j \in C_k} \sum_{l=1}^Q \sum_{n=1}^Q \alpha_{il}^0 \alpha_{jn}^0 \kappa(x_i, x_j) - 2 \sum_{x_i \in C_k} \sum_{j=1}^m \sum_{l=1}^Q \alpha_{il}^0 \alpha_{jk}^0 \kappa(x_i, x_j) + \sum_{i=1}^m \sum_{j=1}^m \alpha_{ik}^0 \alpha_{jk}^0 \kappa(x_i, x_j). \end{aligned}$$

Summing over the index  $k$  thus gives:

$$\begin{aligned} \sum_{k=1}^Q \|w_k^0\|^2 = & \sum_{i \simeq j} \sum_{k=1}^Q \sum_{l=1}^Q \alpha_{ik}^0 \alpha_{jl}^0 \kappa(x_i, x_j) - 2 \sum_{i=1}^m \sum_{j=1}^m \sum_{k=1}^Q \alpha_{ik}^0 \alpha_{jk}^0 \kappa(x_i, x_j) + \sum_{i=1}^m \sum_{j=1}^m \sum_{k=1}^Q \alpha_{ik}^0 \alpha_{jk}^0 \kappa(x_i, x_j). \end{aligned} \quad (38)$$

Still using (25), we find

$$\begin{aligned} \alpha_{ik}^0 \langle w_{C(x_i)}^0 - w_k^0, \Phi(x_i) \rangle = & \sum_{x_j \in C(x_i)} \sum_{l=1}^Q \alpha_{ik}^0 \alpha_{jl}^0 \kappa(x_i, x_j) - \sum_{j=1}^m \alpha_{ik}^0 \alpha_{jk}^0 \kappa(x_i, x_j) \\ & - \sum_{x_j \in C_k} \sum_{l=1}^Q \alpha_{ik}^0 \alpha_{jl}^0 \kappa(x_i, x_j) + \sum_{j=1}^m \alpha_{ik}^0 \alpha_{jk}^0 \kappa(x_i, x_j). \end{aligned}$$

Summing over the index  $k$  gives:

$$\begin{aligned} \sum_{k=1}^Q \alpha_{ik}^0 \langle w_{C(x_i)}^0 - w_k^0, \Phi(x_i) \rangle = & \sum_{x_j \in C(x_i)} \sum_{k=1}^Q \sum_{l=1}^Q \alpha_{ik}^0 \alpha_{jl}^0 \kappa(x_i, x_j) - \sum_{j=1}^m \sum_{k=1}^Q \alpha_{ik}^0 \alpha_{jk}^0 \kappa(x_i, x_j) \\ & - \sum_{j=1}^m \sum_{l=1}^Q \alpha_{iC(x_j)}^0 \alpha_{jl}^0 \kappa(x_i, x_j) + \sum_{j=1}^m \sum_{k=1}^Q \alpha_{ik}^0 \alpha_{jk}^0 \kappa(x_i, x_j). \end{aligned}$$

Summing over the index  $i$  gives:

$$\sum_{i=1}^m \sum_{k=1}^Q \alpha_{ik}^0 \langle w_{C(x_i)}^0 - w_k^0, \Phi(x_i) \rangle =$$

$$\begin{aligned}
& \sum_{i \simeq j} \sum_{k=1}^Q \sum_{l=1}^Q \alpha_{ik}^0 \alpha_{jl}^0 \kappa(x_i, x_j) - \sum_{i=1}^m \sum_{j=1}^m \sum_{k=1}^Q \alpha_{ik}^0 \alpha_{jC(x_i)}^0 \kappa(x_i, x_j) \\
& - \sum_{i=1}^m \sum_{j=1}^m \sum_{l=1}^Q \alpha_{iC(x_j)}^0 \alpha_{jl}^0 \kappa(x_i, x_j) + \sum_{i=1}^m \sum_{j=1}^m \sum_{k=1}^Q \alpha_{ik}^0 \alpha_{jk}^0 \kappa(x_i, x_j) = \\
& \sum_{i \simeq j} \sum_{k=1}^Q \sum_{l=1}^Q \alpha_{ik}^0 \alpha_{jl}^0 \kappa(x_i, x_j) - 2 \sum_{i=1}^m \sum_{j=1}^m \sum_{k=1}^Q \alpha_{ik}^0 \alpha_{jC(x_i)}^0 \kappa(x_i, x_j) + \sum_{i=1}^m \sum_{j=1}^m \sum_{k=1}^Q \alpha_{ik}^0 \alpha_{jk}^0 \kappa(x_i, x_j).
\end{aligned} \tag{39}$$

From (38) and (39), it springs that:

$$\sum_{i=1}^m \sum_{k=1}^Q \alpha_{ik}^0 (\langle w_{C(x_i)}^0 - w_k^0, \Phi(x_i) \rangle) = \sum_{k=1}^Q \|w_k^0\|^2, \tag{40}$$

which, by substitution in (37), provides us with the announced result.

- $\sum_{k=1}^Q \|w_k\|^2 = \sum_{i=1}^m \sum_{k=1}^Q \alpha_{ik}$ .  
Since by hypothesis all the  $\xi_{ik}$  are null, one of the Kuhn-Tucker conditions is:

$$\alpha_{ik}^0 \left\{ \langle w_{C(x_i)}^0 - w_k^0, \Phi(x_i) \rangle + b_{C(x_i)}^0 - b_k^0 - 1 \right\} = 0,$$

and thus:

$$\sum_{i=1}^m \sum_{k=1}^Q \alpha_{ik}^0 \left\{ \langle w_{C(x_i)}^0 - w_k^0, \Phi(x_i) \rangle + b_{C(x_i)}^0 - b_k^0 - 1 \right\} = 0.$$

Recalling (36) and (40), this directly leads to:

$$\begin{aligned}
& \sum_{i=1}^m \sum_{k=1}^Q \alpha_{ik}^0 \left\{ \langle w_{C(x_i)}^0 - w_k^0, \Phi(x_i) \rangle + b_{C(x_i)}^0 - b_k^0 - 1 \right\} = \\
& \sum_{k=1}^Q \|w_k^0\|^2 - \sum_{i=1}^m \sum_{k=1}^Q \alpha_{ik}^0 = 0.
\end{aligned}$$

- $\sum_{k=1}^Q \|w_k^0\|^2 = \frac{1}{Q} \sum_{k < l} \frac{(1 + \delta_{kl})^2}{\gamma_{kl}^2}$   
This is deduced from combining (30) and (33).

■

## 5 Multi-class radius-margin bound

### 5.1 Key lemma in the multi-class case

We now deal with the extension of the key lemma in the multi-class context.

**Lemma 2** *Let us consider a multi-class SVM on a domain  $\mathcal{X}$ . Let  $\mathcal{C} = \{C_k\}$ ,  $(1 \leq k \leq Q)$  be the set of categories. This M-SVM is characterized by a kernel  $\kappa$  (a projection operator  $\Phi$ ) and a soft margin constant  $C$ . Suppose that it is trained on a set  $s_m = \{(x_i, C(x_i))\}$ ,  $(1 \leq i \leq m)$  of  $m$  couples in  $\mathcal{X} \times \mathcal{C}$ , which it discriminates without error. Suppose further that all the corresponding dual variables  $\alpha_{ik}^0$  satisfy  $\alpha_{ik}^0 < C$ . Consider now the same machine, trained on  $s_m \setminus \{(x_p, C(x_p))\}$  (the corresponding dual variables are  $\alpha_{ik}^p$ ). If it makes an error on  $(x_p, C(x_p))$ , classifying this example in category  $C_n$ , then the inequality*

$$\alpha_{pn}^0 \geq \frac{1}{K \mathcal{D}_m^2} \quad (41)$$

holds, where  $\mathcal{D}_m$  is the diameter of the smallest sphere containing the projections of the support vectors in the feature space.  $K$  is defined, using the support vectors, as:

$$K = \sqrt{\max_{i,k : \alpha_{ik}^0 > 0} (K_{\lambda,i,k} \cdot K_{\mu,i,k})}, \quad (42)$$

where  $\lambda = [\lambda_{ik}] \in \mathbb{R}_+^{Qm}$ ,  $\lambda_{iC(x_i)} = 0$ ,  $(1 \leq i \leq m)$ , and  $K_{\lambda,i,k}$  is the value of the objective function at the optimal solution of the QP problem:

**Problem 5**

$$\begin{aligned} & \min_{\lambda} J_{ik}(\lambda) \\ \text{s.t. } & \begin{cases} \forall l, \lambda_{il} = \frac{\alpha_{il}^0}{\alpha_{ik}^0} \\ \forall j \neq i, \forall l, 0 \leq \lambda_{jl} \leq \frac{\alpha_{jl}^0}{\alpha_{ik}^0} \\ \sum_{x_j \in C_l} \sum_{o=1}^Q \lambda_{jo} - \sum_{q=1}^m \lambda_{ql} = 0, \quad (1 \leq l \leq Q-1) \end{cases} \end{aligned}$$

with

$$J_{ik}(\lambda) = \sum_{l=1}^Q \left( \sum_{j=1}^m \lambda_{jl} \right)^2.$$

$\mu = [\mu_{ik}] \in \mathbb{R}_+^{mQ}$ ,  $\mu_{iC(x_i)} = 0$ ,  $(1 \leq i \leq m)$ , and  $K_{\mu,i,k}$  is the value of the objective function at the optimal solution of the QP problem:

**Problem 6**

$$\min_{\mu} J_{ik}(\mu)$$

$$\begin{cases} \begin{cases} l = k, & \mu_{il} = 1 \\ l \neq k & \mu_{il} = 0 \end{cases} \\ \forall j \neq i, \forall l, \mu_{jl} \geq 0 \\ \sum_{x_j \in C_l} \sum_{o=1}^Q \mu_{jo} - \sum_{q=1}^m \mu_{ql} = 0, \quad (1 \leq l \leq Q-1) \end{cases}$$

$J_{ik}$  is defined as for  $\lambda$ :

$$J_{ik}(\mu) = \sum_{l=1}^Q \left( \sum_{j=1}^m \mu_{jl} \right)^2.$$

**Proof** Let  $(W^p, b^p)$  be the couple characterizing the hyperplanes when the machine is trained on  $s_m \setminus \{(x_p, C(x_p))\}$ . Let

$$\alpha^p = [\alpha_{11}^p, \dots, \alpha_{(p-1)Q}^p, 0, \dots, 0, \alpha_{(p+1)1}^p, \dots, \alpha_{mQ}^p]^T$$

be the vector of  $[0, C]^{mQ}$  the components of which are the dual variables of the second M-SVM, with  $\alpha_{pk}^p = 0$ ,  $(1 \leq k \leq Q)$ . This representation is used to characterize directly the second M-SVM with respect to the first one. Indeed,  $\alpha^p$  is an optimal solution of Problem 4 under the additional constraint  $\alpha_{pk}^p = 0$ ,  $(1 \leq k \leq Q)$ . Let us define two more vectors in  $\mathbb{R}_+^{mQ}$ ,  $\lambda^p = [\lambda_{ik}^p]$  and  $\mu^p = [\mu_{ik}^p]$   $(1 \leq i \leq m), (1 \leq k \leq Q)$ , with  $\lambda_{iC(x_i)}^p = \mu_{iC(x_i)}^p = 0$ ,  $(1 \leq i \leq m)$ .  $\lambda^p$  satisfies additional properties so that the vector  $\alpha^0 - \alpha_{pn}^0 \lambda^p$  is a feasible solution of Problem 4 under the additional constraint that  $\alpha_{pk}^0 - \alpha_{pn}^0 \lambda_{pk}^p = 0$ ,  $(1 \leq k \leq Q)$ , i.e.  $\alpha^0 - \alpha_{pn}^0 \lambda^p$  satisfies the same constraints as  $\alpha^p$ . We have thus:

$$\forall i \neq p, \forall k \neq C(x_i), \quad \alpha_{ik}^0 - \alpha_{pn}^0 \lambda_{ik}^p \geq 0 \iff \lambda_{ik}^p \leq \frac{\alpha_{ik}^0}{\alpha_{pn}^0}$$

$$\forall i \neq p, \forall k \neq C(x_i), \quad \lambda_{ik}^p \geq 0 \implies \alpha_{ik}^0 - \alpha_{pn}^0 \lambda_{ik}^p \leq C$$

$$\forall k, \quad \alpha_{pk}^0 - \alpha_{pn}^0 \lambda_{pk}^p = 0 \iff \lambda_{pk}^p = \frac{\alpha_{pk}^0}{\alpha_{pn}^0}$$

$$\sum_{x_i \in C_k} \sum_{l=1}^Q (\alpha_{il}^0 - \alpha_{pn}^0 \lambda_{il}^p) - \sum_{i=1}^m (\alpha_{ik}^0 - \alpha_{pn}^0 \lambda_{ik}^p) = 0 \iff$$

$$\sum_{x_i \in C_k} \sum_{l=1}^Q \lambda_{il}^p - \sum_{i=1}^m \lambda_{ik}^p = 0.$$

To sum up, vector  $\lambda^p$  satisfies the following properties:

$$\begin{cases} \forall k, \quad \lambda_{pk}^p = \frac{\alpha_{pk}^0}{\alpha_{pn}^0} \\ \forall i \neq p, \forall k, \quad 0 \leq \lambda_{ik}^p \leq \frac{\alpha_{ik}^0}{\alpha_{pn}^0} \\ \sum_{x_i \in C_k} \sum_{l=1}^Q \lambda_{il}^p - \sum_{i=1}^m \lambda_{ik}^p = 0, \quad (1 \leq k \leq Q-1) \end{cases}. \quad (43)$$

$\mu^p$  is specified so that  $\alpha^p + c\mu^p$  satisfies the same constraints as  $\alpha^0$ , where  $c$  is a scalar belonging to  $(0, C]$ . Furthermore, we impose that  $\mu_{pk}^p = 0$  for  $k$  different from  $n$  and  $\mu_{pn}^p = 1$ .

$$\begin{aligned} \forall i \neq p, \forall k \neq C(x_i), \quad \mu_{ik}^p \geq 0 &\implies \alpha_{ik}^p + c\mu_{ik}^p \geq 0 \\ \forall i \neq p, \forall k \neq C(x_i), \quad \alpha_{ik}^p + c\mu_{ik}^p \leq C &\iff \mu_{ik}^p \leq \frac{C - \alpha_{ik}^p}{c} \\ \sum_{x_i \in C_k} \sum_{l=1}^Q (\alpha_{il}^p + c\mu_{il}^p) - \sum_{i=1}^m (\alpha_{ik}^p + c\mu_{ik}^p) = 0 &\iff \sum_{x_i \in C_k} \sum_{l=1}^Q \mu_{il}^p - \sum_{i=1}^m \mu_{ik}^p = 0. \end{aligned}$$

Remember that since we can choose an arbitrary large  $C$ , the constraint  $\mu_{ik}^p \leq \frac{C - \alpha_{ik}^p}{c}$  vanishes. To sum up, vector  $\mu^p$  satisfies the following properties:

$$\left\{ \begin{array}{l} k = n, \quad \mu_{ik}^p = 1 \\ k \neq n \quad \mu_{ik}^p = 0 \\ \forall i \neq p, \forall k, \quad \mu_{ik}^p \geq 0 \\ \sum_{x_i \in C_k} \sum_{l=1}^Q \mu_{il}^p - \sum_{i=1}^m \mu_{ik}^p = 0, \quad (1 \leq k \leq Q-1) \end{array} \right. . \quad (44)$$

By construction of vectors  $\lambda^p$  and  $\mu^p$ , we have  $J(\alpha^0 - \alpha_{pn}^0 \lambda^p) \leq J(\alpha^p)$  and  $J(\alpha^p + c\mu^p) \leq J(\alpha^0)$ , and by way of consequence,

$$J(\alpha^0) - J(\alpha^0 - \alpha_{pn}^0 \lambda^p) \geq J(\alpha^0) - J(\alpha^p) \geq J(\alpha^p + c\mu^p) - J(\alpha^p). \quad (45)$$

Since

$$J(\alpha^0 - \alpha_{pn}^0 \lambda^p) = -\frac{1}{2}(\alpha^0 - \alpha_{pn}^0 \lambda^p)^T H(\alpha^0 - \alpha_{pn}^0 \lambda^p) + 1^T(\alpha^0 - \alpha_{pn}^0 \lambda^p)$$

the expression of the first term is

$$J(\alpha^0) - J(\alpha^0 - \alpha_{pn}^0 \lambda^p) = \frac{(\alpha_{pn}^0)^2}{2} \lambda^{pT} H \lambda^p + \alpha_{pn}^0 \lambda^{pT} (1 - H\alpha^0).$$

But recalling (31) we can simplify:

$$\lambda^{pT} (1 - H\alpha^0) = \sum_{i=1}^m \sum_{k \neq C(x_i)} (b_{C(x_i)} - b_k) \lambda_{ik}^p + \sum_{i=1}^m \sum_{k \neq C(x_i)} \lambda_{ik}^p \xi_{ik}^0.$$

But

$$\sum_{i=1}^m \sum_{k \neq C(x_i)} (b_{C(x_i)} - b_k) \lambda_{ik}^p = \sum_{l=1}^Q \left( \sum_{x_i \in C_l} \sum_{k \neq l} \lambda_{ik}^p - \sum_{x_i \notin C_l} \lambda_{il}^p \right) b_l = 0,$$

thus

$$\lambda^{pT} (1 - H\alpha^0) = \sum_{i=1}^m \sum_{k \neq C(x_i)} \lambda_{ik}^p \xi_{ik}^0.$$

At this point, we make use of the hypothesis that all the dual variables  $\alpha_{ik}^0$  are strictly inferior to  $C$ . According to the Kuhn-Tucker conditions, this implies that all the slack variables  $\xi_{ik}^0$  are equal to 0. Thus, the expression of  $J(\alpha^0) - J(\alpha^0 - \alpha_{pn}^0 \lambda^p)$  is simply

$$J(\alpha^0) - J(\alpha^0 - \alpha_{pn}^0 \lambda^p) = \frac{(\alpha_{pn}^0)^2}{2} \lambda^{pT} H \lambda^p.$$

Using (34), we find

$$J(\alpha^0) - J(\alpha^0 - \alpha_{pn}^0 \lambda^p) = \frac{(\alpha_{pn}^0)^2}{2} \sum_{k=1}^Q \left\| \sum_{x_i \in C_k} \sum_{l=1}^Q \lambda_{il}^p \Phi(x_i) - \sum_{i=1}^m \lambda_{ik}^p \Phi(x_i) \right\|^2. \quad (46)$$

We turn now to the right-hand side of (45).

$$J(\alpha^p + c\mu^p) - J(\alpha^p) = c\mu^{pT} (1 - H\alpha^p) - \frac{c^2}{2} \sum_{k=1}^Q \left\| \sum_{x_i \in C_k} \sum_{l=1}^Q \mu_{il}^p \Phi(x_i) - \sum_{i=1}^m \mu_{ik}^p \Phi(x_i) \right\|^2.$$

Proceeding as in the case of the left-hand side of (45), we establish that

$$\mu^{pT} (1 - H\alpha^p) = \sum_{i=1}^m \sum_{k \neq C(x_i)} \mu_{ik}^p \xi_{ik}^p.$$

If the initial SVM, characterized by the couple  $(W^0, b^0)$ , has nothing but null slack variables, then the sole slack variables of the SVM  $(W^p, b^p)$  which can be positive are thoses associated with  $x_p$ , i.e. the variables  $\xi_{pk}^p$ ,  $(1 \leq k \neq C(x_p) \leq Q)$ . Thus,

$$\mu^{pT} (1 - H\alpha^p) = \sum_{k \neq C(x_p)} \mu_{pk}^p \xi_{pk}^p.$$

Since  $\mu_{pk}^p = 0$  for  $k \neq n$  and  $\mu_{pn}^p = 1$ , this simplifies into:

$$\mu^{pT} (1 - H\alpha^p) = \xi_{pn}^p = 1 - \langle w_{C(x_p)} - w_n, \Phi(x_p) \rangle - b_{C(x_p)} + b_n$$

and by way of consequence

$$J(\alpha^p + c\mu^p) - J(\alpha^p) = c [1 - \langle w_{C(x_p)} - w_n, \Phi(x_p) \rangle - b_{C(x_p)} + b_n] -$$

$$\frac{c^2}{2} \sum_{k=1}^Q \left\| \sum_{x_i \in C_k} \sum_{l=1}^Q \mu_{il}^p \Phi(x_i) - \sum_{i=1}^m \mu_{ik}^p \Phi(x_i) \right\|^2. \quad (47)$$

Combining (46) and (47) finally gives:

$$\frac{(\alpha_{pn}^0)^2}{2} \sum_{k=1}^Q \left\| \sum_{x_i \in C_k} \sum_{l=1}^Q \lambda_{il}^p \Phi(x_i) - \sum_{i=1}^m \lambda_{ik}^p \Phi(x_i) \right\|^2 \geq$$

$$c \left[ 1 - \langle w_{C(x_p)} - w_n, \Phi(x_p) \rangle - b_{C(x_p)} + b_n \right] - \frac{c^2}{2} \sum_{k=1}^Q \left\| \sum_{x_i \in C_k} \sum_{l=1}^Q \mu_{il}^p \Phi(x_i) - \sum_{i=1}^m \mu_{ik}^p \Phi(x_i) \right\|^2. \quad (48)$$

The value of the scalar  $c$  maximizing the right-hand side of (48) is:

$$c^* = \frac{[1 - \langle w_{C(x_p)} - w_n, \Phi(x_p) \rangle - b_{C(x_p)} + b_n]}{\sum_{k=1}^Q \left\| \sum_{x_i \in C_k} \sum_{l=1}^Q \mu_{il}^p \Phi(x_i) - \sum_{i=1}^m \mu_{ik}^p \Phi(x_i) \right\|^2}.$$

By substitution in (48), this means that  $(\alpha_{pn}^0)^2$  can be bounded from below as follows:

$$(\alpha_{pn}^0)^2 \geq \frac{[1 - \langle w_{C(x_p)} - w_n, \Phi(x_p) \rangle - b_{C(x_p)} + b_n]^2}{\sum_{k=1}^Q \left\| \sum_{x_i \in C_k} \sum_{l=1}^Q \lambda_{il}^p \Phi(x_i) - \sum_{i=1}^m \lambda_{ik}^p \Phi(x_i) \right\|^2 \sum_{k=1}^Q \left\| \sum_{x_i \in C_k} \sum_{l=1}^Q \mu_{il}^p \Phi(x_i) - \sum_{i=1}^m \mu_{ik}^p \Phi(x_i) \right\|^2}.$$

Since by hypothesis, the SVM  $(W^p, b^p)$  makes an error on  $x_p$ , classifying it in the category  $C_n$ ,

$$\langle w_{C(x_p)} - w_n, \Phi(x_p) \rangle + b_{C(x_p)} + b_n < 0$$

and thus

$$[1 - \langle w_{C(x_p)} - w_n, \Phi(x_p) \rangle - b_{C(x_p)} + b_n]^2 > 1.$$

This provides us with a simpler lower bound on  $(\alpha_{pn}^0)^2$ , namely

$$(\alpha_{pn}^0)^2 \geq \frac{1}{\sum_{k=1}^Q \left\| \sum_{x_i \in C_k} \sum_{l=1}^Q \lambda_{il}^p \Phi(x_i) - \sum_{i=1}^m \lambda_{ik}^p \Phi(x_i) \right\|^2 \sum_{k=1}^Q \left\| \sum_{x_i \in C_k} \sum_{l=1}^Q \mu_{il}^p \Phi(x_i) - \sum_{i=1}^m \mu_{ik}^p \Phi(x_i) \right\|^2}. \quad (49)$$

Let  $K_{\lambda,p,n,k}$  be:

$$K_{\lambda,p,n,k} = \sum_{i=1}^m \lambda_{ik}^p.$$

We have:

$$\left\| \sum_{x_i \in C_k} \sum_{l=1}^Q \lambda_{il}^p \Phi(x_i) - \sum_{i=1}^m \lambda_{ik}^p \Phi(x_i) \right\|^2 = (K_{\lambda,p,n,k})^2 \|Cv_1(\Phi(x_i)) - Cv_2(\Phi(x_i))\|^2$$

where  $Cv_1(\Phi(x_i))$  and  $Cv_2(\Phi(x_i))$ , as in the bi-class case, are two convex combinations the difference of which we can bound by  $\mathcal{D}_m$ . Then,

$$\sum_{k=1}^Q \left\| \sum_{x_i \in C_k} \sum_{l=1}^Q \lambda_{il}^p \Phi(x_i) - \sum_{i=1}^m \lambda_{ik}^p \Phi(x_i) \right\|^2 \leq \mathcal{D}_m^2 \sum_{k=1}^Q (K_{\lambda,p,n,k})^2.$$

Since the same reasoning can be done with vector  $\mu^p$  in place of the vector  $\lambda^p$ , with  $K_{\mu,p,n,k}$  replacing  $K_{\lambda,p,n,k}$ , this leads to

$$(\alpha_{pn}^0)^2 \geq \frac{1}{\mathcal{D}_m^4 \sum_{k=1}^Q (K_{\lambda,p,n,k})^2 \sum_{k=1}^Q (K_{\mu,p,n,k})^2}.$$

By construction,  $\lambda^p$  and  $\mu^p$  satisfy the constraints of Problems 5 and 6 respectively. As a consequence, they can be chosen so that  $\sum_{k=1}^Q (K_{\lambda,p,n,k})^2 = K_{\lambda,p,n}^2$  and  $\sum_{k=1}^Q (K_{\mu,p,n,k})^2 = K_{\mu,p,n}^2$ . By definition of constant  $K$ , we then get:

$$\sum_{k=1}^Q (K_{\lambda,p,n,k})^2 \sum_{k=1}^Q (K_{\mu,p,n,k})^2 \leq K^2$$

and finally:

$$(\alpha_{pn}^0)^2 \geq \frac{1}{\mathcal{D}_m^4 K^2}.$$

Taking the square root concludes the proof of the lemma. ■

## 5.2 MC-RM theorem

**Theorem 2** *Let us consider a multi-class SVM on a domain  $\mathcal{X}$ . Let  $\mathcal{C} = \{C_k\}$ , ( $1 \leq k \leq Q$ ) be the set of categories. This M-SVM is characterized by a kernel  $\kappa$  (a projection operator  $\Phi$ ) and a soft margin constant  $C$ . Suppose that it is trained on a set  $s_m = \{(x_i, C(x_i))\}$ , ( $1 \leq i \leq m$ ) of  $m$  couples in  $\mathcal{X} \times \mathcal{C}$ , which it discriminates without error. Suppose further that all the corresponding dual variables  $\alpha_{ik}^0$  satisfy  $\alpha_{ik}^0 < C$ . Let  $\mathcal{L}_m$  be the number of errors resulting from applying a leave-one-out procedure to this machine,  $\mathcal{D}_m$  the diameter of the smallest ball containing the support vectors of the initial machine and  $(\gamma_{kl})_{1 \leq k < l \leq Q}$  its bi-class margins according to Definition 1. Let the  $\delta_{kl}$  be given by (29) and  $K$  be the constant in the key lemma (equation (42)). The following upper bound holds true:*

$$\mathcal{L}_m \leq \frac{K \mathcal{D}_m^2}{Q} \sum_{k < l} \frac{(1 + \delta_{kl})^2}{\gamma_{kl}^2}. \quad (50)$$

**Proof** Actually, the key lemma exhibits a non-trivial bound on  $\alpha_{in}^0$  when the machine trained on the set without  $(x_i, y_i)$  makes an error classifying it in  $C_n$ . Thus, the sum of the  $\alpha_{ik}^0$  is constituted of the terms we can bound thanks to the key lemma ( $\alpha_{ik}^0 \geq \frac{1}{K\mathcal{D}_m^2}$ ) and the others with the trivial bound ( $\alpha_{ik}^0 \geq 0$ ). We have thus:

$$\sum_{i=1}^m \sum_{k=1}^Q \alpha_{ik}^0 \geq \frac{\mathcal{L}_m}{K\mathcal{D}_m^2}$$

and consequently:

$$\mathcal{L}_m \leq K\mathcal{D}_m^2 \sum_{i=1}^m \sum_{k=1}^Q \alpha_{ik}^0.$$

Recalling Proposition 2, we conclude:

$$\mathcal{L}_m \leq K\mathcal{D}_m^2 \frac{1}{Q} \sum_{k < l} \frac{(1 + \delta_{kl})^2}{\gamma_{kl}^2}.$$

■

One could find strange the presence of the  $\frac{1}{Q}$  coefficient in the right-hand side of (50). Indeed, at first sight, it seems that this formula is not equivalent to the one of Theorem 1 when  $Q = 2$ . This is however the case, and the difference springs from the fact that the penalty term in the primal objective function is  $\sum_{k=1}^Q \|w_k\|^2$  instead of  $\sum_{k < l} \|w_k - w_l\|^2$ , the use of which would make the relationship between the bi-class and the multi-class cases more straightforward.

## 6 Conclusions and future work

In this report, we have established a direct extension of the radius-margin bound to the case of the standard multi-class SVM. Obviously, its practical interest primarily depends on the possibility to compute the constant  $K$  at a reasonable cost. This could be the case, since this computation does not involve the computation of the kernel  $\kappa$  on the points of the training set. If so, then the bi-class variant of the bound could even prove superior to Chapelle's one (since it should be tighter by construction). Our result can be directly compared with those proposed in [13], both from the point of view of sharpness and cpu time requirements. This is the subject of an ongoing study.
